# Package: GenomAutomorphism (via r-universe)

September 29, 2024

**Title** Compute the automorphisms between DNA's Abelian group representations

Version 1.7.0

URL https://github.com/genomaths/GenomAutomorphism

BugReports https://github.com/genomaths/GenomAutomorphism/issues

Description This is a R package to compute the automorphisms between pairwise aligned DNA sequences represented as elements from a Genomic Abelian group. In a general scenario, from genomic regions till the whole genomes from a given population (from any species or close related species) can be algebraically represented as a direct sum of cyclic groups or more specifically Abelian p-groups. Basically, we propose the representation of multiple sequence alignments of length N bp as element of a finite Abelian group created by the direct sum of homocyclic Abelian group of prime-power order.

## **Description**

The aminoacid indexes from Amino Acid Index Database https://www.genome.jp/aaindex/ are provided here. AAindex (ver.9.2) is a database of numerical indices representing various physicochemical and biochemical properties of amino acids and pairs of amino acids.

# Usage

```
data("aaindex1", package = "GenomAutomorphism")
```

# **Format**

A list carrying the the description 566 Amino Acid Indices in AAindex ver.9.2 and the text file with the matrices imported from https://www.genome.jp/aaindex/.

## Author(s)

Robersy Sanchez https://genomaths.com

## See Also

aaindex2 and aaindex3.

4 aaindex2

#### **Examples**

```
## Load the mutation matrices from database from the packages
data("aaindex1", package = "GenomAutomorphism", envir = environment())
## Get the available aminoacid indices.
mat <- aa_phychem_index(aaindex = "aaindex1", acc_list = TRUE)
mat[1:10]</pre>
```

aaindex2

List of 94 Amino Acid Matrices from AAindex

## Description

The aminoacid similarity matrices from Amino Acid Index Database https://www.genome.jp/aaindex/ are provided here. AAindex (ver.9.2) is a database of numerical indices representing various physicochemical and biochemical properties of amino acids and pairs of amino acids.

#### Usage

```
data("aaindex2", package = "GenomAutomorphism")
```

#### **Format**

A list carrying the description of 94 Amino Acid Matrices in AAindex ver.9.2 and the text file of matrices imported from <a href="https://www.genome.jp/aaindex/">https://www.genome.jp/aaindex/</a>.

#### **Details**

The similarity of amino acids can be represented numerically, expressed in terms of observed mutation rate or physicochemical properties. A similarity matrix, also called a mutation matrix, is a set of 210 numerical values, 20 diagonal and 20x19/2 off-diagonal elements, used for sequence alignments and similarity searches.

mat[1:10]</pre>
```

aaindex3

Statistical protein contact potentials matrices from AAindex ver.9.2

## **Description**

A statistical potential (also knowledge-based potential, empirical potential, or residue contact potential) is an energy function derived from an analysis of known structures in the Protein Data Bank.

## Usage

```
data("aaindex3", package = "GenomAutomorphism")
```

#### **Format**

A list carrying the the description 47 Amino Acid Matrices in AAindex ver.9.2 and the text file of matrices imported from https://www.genome.jp/aaindex/.

## Details

A list of 47 amino acid matrices from Amino Acid Index Database https://www.genome.jp/aaindex/ are provided here. AAindex is a database of numerical indices representing various physicochemical and biochemical properties of amino acids and pairs of amino acids.

The contact potential matrix of amino acids is a set of 210 numerical values, 20 diagonal and 20x19/2 off-diagonal elements, used for sequence alignments and similarity searches.

# Author(s)

6 aa\_phychem\_index

## **Examples**

```
## Load the mutation matrices from database from the packages
data("aaindex3", package = "GenomAutomorphism")

## Get the available mutation matrices
mat <- aa_mutmat(aaindex = "aaindex3", acc_list = TRUE)
mat[1:10]</pre>
```

aa\_phychem\_index

Amino acid mutation matrix

#### **Description**

The aminoacid similarity matrices from Amino Acid Index Database <a href="https://www.genome.jp/aaindex/">https://www.genome.jp/aaindex/</a> are provided here. AAindex (ver.9.2) is a database of numerical indices representing various physicochemical and biochemical properties of amino acids and pairs of amino acids.

The similarity of amino acids can be represented numerically, expressed in terms of observed mutation rate or physicochemical properties. A similarity matrix, also called a mutation matrix, is a set of 210 numerical values, 20 diagonal and 20x19/2 off-diagonal elements, used for sequence alignments and similarity searches.

Function *aa\_phychem\_index* is wrapper function to call two other functions: *aa\_mutmat* and *aa\_index* 

## Usage

```
aa_phychem_index(acc = NA, aaindex = NA, acc_list = FALSE, info = FALSE)
aa_mutmat(acc = NA, aaindex = c("aaindex2", "aaindex3"), acc_list = FALSE)
aa_index(acc = NA, acc_list = FALSE, info = FALSE)
```

## **Arguments**

acc	Accession id for a specified mutation or contact potential matrix.
aaindex	Database where the requested accession id is locate. The possible values are: "aaindex2" or "aaindex3".
acc_list	Logical. If TRUE, then the list of available matrices ids and index names is returned.
info	Logical. if TRUE, then whole information for the physicochemical index will be returned.

aln 7

#### Value

Depending on the user specifications, a mutation or contact potential matrix, a list of available matrices (indices) ids or index names can be returned. More specifically:

aa\_mutmat: Returns an aminoacid mutation matrix or a statistical protein contact potentials matrix.

aa\_index: Returns the specified aminoacid physicochemical indices.

#### Author(s)

```
Robersy Sanchez https://genomaths.com
```

#### See Also

```
aaindex1, aaindex2, aaindex3, and get_mutscore.
```

#### **Examples**

```
## Load the mutation matrices from database from the packages
data("aaindex1","aaindex2", package = "GenomAutomorphism")

## Get the available mutation matrices
mat <- aa_mutmat(aaindex = "aaindex2", acc_list = TRUE)
mat[seq(10)]

## Return the 'Base-substitution-protein-stability matrix
## (Miyazawa-Jernigan, 1993)'
aa_mutmat(acc = "MIYS930101", aaindex = "aaindex2")

## Return the 'BLOSUM80 substitution matrix (Henikoff-Henikoff, 1992)'
aa_mutmat(acc = "HENS920103", aaindex = "aaindex2")

## Using wrapping function
aa_phychem_index(acc = "EISD840101", aaindex = "aaindex1")

## Just the info. The information provided after the reference
## corresponds to the correlaiton of 'EISD840101' with other indices.
aa_phychem_index(acc = "EISD840101", aaindex = "aaindex1", info = TRUE)</pre>
```

aln

Simulated DNAStringSet class object

## **Description**

This is a DNAStringSet carrying a small pairwise DNA sequence alignment to be used in the examples provided for the package functions.

8 aminoacid\_dist

#### Usage

```
data("aln", package = "GenomAutomorphism")
```

#### **Format**

DNAStringSet class object.

#### **Examples**

```
data("aln", package = "GenomAutomorphism")
aln
```

aminoacid\_dist

Distance Between Aminoacids in Terms of Codon Distance

## **Description**

This function computes the distance between aminoacids in terms of a statistic of the corresponding codons. The possible statistics are: 'mean', 'median', or some user defined function.

## Usage

```
aminoacid_dist(aa1, aa2, ...)
## S4 method for signature 'character, character'
aminoacid_dist(
  aa1,
  aa2,
 weight = NULL,
  stat = c("mean", "median", "user_def"),
  genetic_code = "1",
 group = c("Z4", "Z5"),
 cube = c("ACGT", "AGCT", "TCGA", "TGCA", "CATG", "GTAC", "CTAG", "GATC", "ACTG",
   "ATCG", "GTCA", "GCTA", "CAGT", "TAGC", "TGAC", "CGAT", "AGTC", "ATGC", "CGTA",
    "CTGA", "GACT", "GCAT", "TACG", "TCAG"),
  num.cores = 1L,
  tasks = 0L,
  verbose = FALSE
)
## S4 method for signature 'DNAStringSet, ANY'
aminoacid_dist(
  aa1,
 weight = NULL,
  stat = c("mean", "median", "user_def"),
  group = c("Z4", "Z5"),
```

aminoacid\_dist 9

```
cube = c("ACGT", "AGCT", "TCGA", "TGCA", "CATG", "GTAC", "CTAG", "GATC", "ACTG",
   "ATCG", "GTCA", "GCTA", "CAGT", "TAGC", "TGAC", "CGAT", "AGTC", "ATGC", "CGTA",
    "CTGA", "GACT", "GCAT", "TACG", "TCAG"),
  num.cores = 1L,
  tasks = 0L,
  verbose = FALSE
)
## S4 method for signature 'AAStringSet,ANY'
aminoacid_dist(
  aa1,
 weight = NULL,
  stat = c("mean", "median", "user_def"),
  group = c("Z4", "Z5"),
 cube = c("ACGT", "AGCT", "TCGA", "TGCA", "CATG", "GTAC", "CTAG", "GATC", "ACTG",
  "ATCG", "GTCA", "GCTA", "CAGT", "TAGC", "TGAC", "CGAT", "AGTC", "ATGC", "CGTA",
    "CTGA", "GACT", "GCAT", "TACG", "TCAG"),
  num.cores = 1L,
  tasks = 0L,
  verbose = FALSE
)
## S4 method for signature 'CodonGroup_OR_Automorphisms, ANY'
aminoacid_dist(
  aa1,
 weight = NULL,
  stat = c("mean", "median", "user_def"),
  group = c("Z4", "Z5"),
 cube = c("ACGT", "AGCT", "TCGA", "TGCA", "CATG", "GTAC", "CTAG", "GATC", "ACTG",
  "ATCG", "GTCA", "GCTA", "CAGT", "TAGC", "TGAC", "CGAT", "AGTC", "ATGC", "CGTA",
    "CTGA", "GACT", "GCAT", "TACG", "TCAG"),
  num.cores = 1L,
  tasks = 0L,
  verbose = FALSE
```

#### **Arguments**

stat

aa1, aa2 A character string of codon sequences, i.e., sequences of DNA base-triplets. If only 'x' argument is given, then it must be a DNAStringSet-class object.

... Not in use yet.

weight A numerical vector of weights to compute weighted Manhattan distance between codons. If weight = NULL, then weight = (1/4, 1, 1/16) for group = (1/4, 1, 1/16)

"Z4" and weight = (1/5, 1, 1/25) for group = "Z5" (see codon\_dist).

The name of some statistical function summarizing data like 'mean', 'median', or some user defined function ('user\_def'). If  $stat = 'user_def'$ , then function must have a logical argument named 'na.rm' addressed to remove missing (NA) data (see e.g., mean).

10 aminoacid\_dist

genetic\_code A single string that uniquely identifies the genetic code to extract. Should be

one of the values in the id or name2 columns of GENETIC\_CODE\_TABLE.

group A character string denoting the group representation for the given codon se-

quence as shown in reference (2-3).

cube A character string denoting one of the 24 Genetic-code cubes, as given in refer-

ences (2-3).

num.cores, tasks

Parameters for parallel computation using package BiocParallel-package: the number of cores to use, i.e. at most how many child processes will be run simultaneously (see bplapply and the number of tasks per job (only for Linux

OS).

verbose If TRUE, prints the progress bar.

#### **Details**

Only aminoacids sequences given in the following alphabet are accepted: "A","R","N","D","C","Q","E","G","H","I","K" "M","F","P", "S","T","W","Y","V", "", "-", and "X"; where symbols "" and "-" denote the presence a stop codon and of a gap, respectively, and letter "X" missing information, which are then taken as a gap.

The distance between any aminoacid and any of the non-aminoacid symbols is the ceiling of the greater distance found in the corresponding aminoacid distance matrix.

## Value

A numerical vector with the pairwise distances between codons in sequences 'x' and 'y'.

```

aut3D

Compute the Automorphisms of Mutational Events Between two Codon Sequences Represented in Z5<sup>3</sup>.

## **Description**

Given two codon sequences represented in the Z5<sup>3</sup> Abelian group, this function computes the automorphisms describing codon mutational events.

# Usage

```
aut3D(
    seq = NULL,
    filepath = NULL,
    cube = c("ACGT", "TGCA"),
    cube_alt = c("CATG", "GTAC"),
    field = "GF5",
    start = NA,
    end = NA,
    chr = 1L,
    strand = "+",
    genetic_code = getGeneticCode("1"),
    num.cores = multicoreWorkers(),
    tasks = 0L,
    verbose = TRUE
)
```

#### **Arguments**

seq

An object from a DNAStringSet or DNAMultipleAlignment class carrying the DNA pairwise alignment of two sequences. The pairwise alignment provided in argument **seq** or the 'fasta' file **filepath** must correspond to codon sequences.

aut3D 13

filepath A character vector containing the path to a file in **fasta** format to be read. This

argument must be given if *codon & base* arguments are not provided.

cube, cube\_alt A character string denoting pairs of the 24 Genetic-code cubes, as given in refer-

ences (2-3). That is, the base pairs from the given cubes must be complementary each other. Such a cube pair are call dual cubes and, as shown in reference (3),

each pair integrates group.

field A character string denoting the Galois field where the 3D automorphisms are

estimated. This can be 'GF(4)' or 'GF(5)', but only 'GF(5)' is implemented so

rar.

start, end, chr, strand

Optional parameters required to build a GRanges-class. If not provided the default values given for the function definition will be used.

genetic\_code The named character vector returned by getGeneticCode or similar. The trans-

lation of codon into aminoacids is a valuable information useful for downstream statistical analysis. The standard genetic code is the default argument value ap-

plied in the translation of codons into aminoacids (see GENETIC\_CODE\_TABLE.

num.cores, tasks

Parameters for parallel computation using package BiocParallel-package: the number of cores to use, i.e. at most how many child processes will be run simultaneously (see bplapply and the number of tasks per job (only for Linux

OS).

verbose If TRUE, prints the progress bar.

#### **Details**

Automorphisms in Z5<sup>3</sup> are described as functions f(x) = AxmodZ5, where A is diagonal matrix, as noticed in reference (4).

#### Value

An object Automorphism-class with four columns on its metacolumn named: *seq1*, *seq2*, *autm*, and *cube*.

autm\_z125

Automorphisms between DNA Sequences from two COVID-19 genomes

# Description

This is a AutomorphismList object carrying a list of pairwise automorphisms between the SARS coronavirus GZ02 (GenBank: AY390556.1: 265-13398\_13398-21485) and Bat SARS-like coronavirus isolate bat-SL-CoVZC45 (GenBank: MG772933.1:265-1345513455-21542), nonstructural\_polyprotein. The pairwise DNA sequence alignment is available in the dataset named covid\_aln and the automorphisms were estimated with function autZ125.

## Usage

```
data("autm_z125", package = "GenomAutomorphism")
```

## Format

AutomorphismList class object.

## **Examples**

```
data("autm_z125", package = "GenomAutomorphism")
autm_z125
```

automorphismByRanges Get the automorphisms by ranges.

# **Description**

Automorphisms estimated on a pairwise or a MSA alignment can be grouped by ranges which inherits from GRanges-class or a GRanges-class.

## **Usage**

```
automorphismByRanges(x, ...)
## S4 method for signature 'Automorphism'
automorphismByRanges(x)
## S4 method for signature 'AutomorphismList'
automorphismByRanges(
    x,
    min.len = 0L,
    num.cores = multicoreWorkers(),
    tasks = 0L,
    verbose = TRUE
)
```

## **Arguments**

x An AutomorphismList-class object returned by function automorphisms.

... Not in use.

min.len Minimum length of a range to be reported.

num.cores, tasks

Integers. Argument num.cores denotes the number of cores to use, i.e. at most how many child processes will be run simultaneously (see bplapply function from BiocParallel package). Argument tasks denotes the number of tasks per job. value must be a scalar integer >= 0L. In this documentation a job is defined as a single call to a function, such as bplapply. A task is the division of the X argument into chunks. When tasks == 0 (default), X is divided as evenly as possible over the number of workers (see MulticoreParam from BiocParallel package).

verbose

logic(1). If TRUE, enable progress bar.

#### Value

A GRanges-class or a GRangesList-class. Each GRanges-class object with a column named *cube*, which carries the type of *cube* automorphims.

```
## Load dataset
data("autm", package = "GenomAutomorphism")
automorphismByRanges(x = autm[c(1, 4)])
```

18 automorphisms

automorphisms

Compute the Automorphisms of Mutational Events Between two Codon Sequences Represented in a Given Abelian group.

# Description

Given two codon sequences represented in a given Abelian group, this function computes the automorphisms describing codon mutational events. Basically, this function is a wrapping to call the corresponding function for a specified Abelian group.

## Usage

```
automorphisms(seqs = NULL, filepath = NULL, group = "Z4", ...)
## S4 method for signature 'DNAStringSet_OR_NULL'
automorphisms(
  seqs = NULL,
  filepath = NULL,
 group = c("Z5", "Z64", "Z125", "Z5^3"),
  cube = c("ACGT", "TGCA"),
  cube_alt = c("CATG", "GTAC"),
  nms = NULL,
  start = NA,
  end = NA,
  chr = 1L,
  strand = "+",
  num.cores = multicoreWorkers(),
  tasks = 0L,
  verbose = TRUE
)
```

#### **Arguments**

seqs	An object from a DNAStringSet or DNAMultipleAlignment class carrying the DNA pairwise alignment of two sequences. The pairwise alignment provided in argument <b>seq</b> or the 'fasta' file <b>filepath</b> must correspond to codon sequences.
filepath	A character vector containing the path to a file in <b>fasta</b> format to be read. This argument must be given if <i>codon &amp; base</i> arguments are not provided.
group	A character string denoting the group representation for the given base or codon as shown in reference (1).
	Not in use.
cube, cube_alt	A character string denoting pairs of the 24 Genetic-code cubes, as given in references (2-3). That is, the base pairs from the given cubes must be complementary each other. Such a cube pair are call <i>dualcubes</i> and, as shown in reference (3), each pair integrates group.

automorphisms 19

nms

Optional. Only used if the DNA sequence alignment provided carries more than two sequences. A character string giving short names for the alignments to be compared. If not given then the automorphisms between pairwise alignment are named as: 'aln\_1', 'aln\_2', and so on.

start, end, chr, strand

Optional parameters required to build a GRanges-class. If not provided the default values given for the function definition will be used.

num.cores, tasks

Parameters for parallel computation using package BiocParallel-package: the number of cores to use, i.e. at most how many child processes will be run simultaneously (see bplapply and the number of tasks per job (only for Linux OS).

verbose

If TRUE, prints the progress bar.

#### **Details**

Herein, automorphisms are algebraic descriptions of mutational event observed in codon sequences represented on different Abelian groups. In particular, as described in references (3-4), for each representation of the codon set on a defined Abelian group there are 24 possible isomorphic Abelian groups. These Abelian groups can be labeled based on the DNA base-order used to generate them. The set of 24 Abelian groups can be described as a group isomorphic to the symmetric group of degree four ( $S_4$ , see reference (4)). Function automorphismByRanges permits the classification of the pairwise alignment of protein-coding sub-regions based on the mutational events observed on it and on the genetic-code cubes that describe them.

Automorphisms in Z5, Z64 and Z125 are described as functions f(x) = kxmod64 and f(x) = kxmod125, where k and x are elements from the set of integers modulo 64 or modulo 125, respectively. If an automorphisms cannot be found on any of the cubes provided in the argument cube, then function automorphisms will search for automorphisms in the cubes provided in the argument  $cube_a lt$ .

Automorphisms in Z5<sup>3</sup> are described as functions f(x) = Ax mod Z5, where A is diagonal matrix

Arguments cube and cube\_alt must be pairs of' dual cubes (see section 2.4 from reference 4).

#### Value

This function returns a Automorphism-class object with four columns on its metacolumn named: seq1, seq2, autm, and cube.

#### Methods

#### automorphismByRanges::

This function returns a GRanges-class object. Consecutive mutational events (on the codon sequence) described by automorphisms on a same cube are grouped in a range.

## automorphism\_bycoef:

This function returns a GRanges-class object. Consecutive mutational events (on the codon sequence) described by the same automorphisms coefficients are grouped in a range.

20 automorphisms

#### getAutomorphisms:

This function returns an AutomorphismList-class object as a list of Automorphism-class objects, which inherits from GRanges-class objects.

## conserved\_regions:

Returns a AutomorphismByCoef class object containing the requested regions.

autms

automorphism\_bycoef

Autmorphism Grouping by Coefficient

# Description

Automorphisms with the same automorphism's coefficients are grouped.

#### Usage

```
automorphism_bycoef(x, ...)
## S4 method for signature 'Automorphism'
automorphism_bycoef(x, mut.type = TRUE)

## S4 method for signature 'AutomorphismList'
automorphism_bycoef(
    x,
    min.len = 1L,
    mut.type = TRUE,
    num.cores = multicoreWorkers(),
    tasks = 0L,
    verbose = TRUE
)
```

#### **Arguments**

x An automorphism-class object returned by function automorphisms.

. . . Not in use.

mut.type Logical. Whether to include the mutation type as given by function mut\_type.

min.len Minimum length of a range to be reported.

num.cores, tasks

Integers. Argument *num.cores* denotes the number of cores to use, i.e. at most how many child processes will be run simultaneously (see bplapply function from BiocParallel package). Argument *tasks* denotes the number of tasks per job. value must be a scalar integer >= 0L. In this documentation a job is defined as a single call to a function, such as bplapply. A task is the division of the X argument into chunks. When tasks == 0 (default), X is divided as evenly as possible over the number of workers (see MulticoreParam from BiocParallel package).

verbose logic(1). If TRUE, enable progress bar.

22 autZ125

#### Value

An AutomorphismByCoef class object. A coefficient with 0 value is assigned to mutational events that are not automorphisms, e.g., indel mutations.

#### See Also

```
automorphisms
```

# Examples

```
## Load dataset
data("autm", package = "GenomAutomorphism")
automorphism_bycoef(x = autm[1:2])
```

autZ125

Compute the Automorphisms of Mutational Events Between two Codon Sequences Represented in Z125.

#### Description

Given two codon sequences represented in the Z125 Abelian group, this function computes the automorphisms describing codon mutational events.

#### Usage

```
autZ125(
    seq = NULL,
    filepath = NULL,
    cube = c("ACGT", "TGCA"),
    cube_alt = c("CATG", "GTAC"),
    start = NA,
    end = NA,
    chr = 1L,
    strand = "+",
    genetic_code = getGeneticCode("1"),
    num.cores = multicoreWorkers() - 1,
    tasks = 0L,
    verbose = TRUE
)
```

#### **Arguments**

seq

An object from a DNAStringSet or DNAMultipleAlignment class carrying the DNA pairwise alignment of two sequences. The pairwise alignment provided in argument **seq** or the 'fasta' file **filepath** must correspond to codon sequences.

autZ125 23

filepath A character vector containing the path to a file in **fasta** format to be read. This argument must be given if *codon & base* arguments are not provided.

cube, cube\_alt A character string denoting pairs of the 24 Genetic-code cubes, as given in references (2-3). That is, the base pairs from the given cubes must be complementary each other. Such a cube pair are call dual cubes and, as shown in reference (3),

each pair integrates group.

start, end, chr, strand

Optional parameters required to build a GRanges-class. If not provided the default values given for the function definition will be used.

genetic\_code The named character vector returned by getGeneticCode or similar. The trans-

lation of codon into aminoacids is a valuable information useful for downstream statistical analysis. The standard genetic code is the default argument value applied in the translation of codons into aminoacids (see GENETIC\_CODE\_TABLE.

num.cores, tasks

Parameters for parallel computation using package BiocParallel-package: the number of cores to use, i.e. at most how many child processes will be run simultaneously (see bplapply and the number of tasks per job (only for Linux OS).

verbose If TRUE, prints the progress bar.

#### **Details**

Automorphisms in Z125 are described as functions f(x) = kx mod 64, where k and x are elements from the set of integers modulo 64. As noticed in reference (1)

## Value

An object Automorphism-class with four columns on its metacolumn named: *seq1*, *seq2*, *autm*, and *cube*.

28 base2codon

base2codon

Split a DNA sequence into codons

## **Description**

This function split a DNA sequence into a codon sequence.

## Usage

```
base2codon(x, ...)
## S4 method for signature 'character'
base2codon(x)
## S4 method for signature 'DNAStringSet'
base2codon(x)
## S4 method for signature 'DNAMultipleAlignment'
base2codon(x)
```

#### Arguments

x A character string, DNAStringSet-class or DNAMultipleAlignment-class object carrying the a DNA sequence.

... Not in use.

#### **Details**

It is expected that the provided DNA sequence is multiple of 3, otherwise gaps are added to the end of the sequence.

#### Value

If the argument of 'x' is character string, then a character vector of codons will returned. If the argument of 'x' is DNAStringSet-class or DNAMultipleAlignment-class object, then a matrix of codons is returned.

#### Author(s)

```
Robersy Sanchez https://genomaths.com. 01/15/2022
```

```
## Gaps are added at the sequence end.
seq <- c("ACCT")
base2codon(x = seq)
## This DNA sequence is multiple of 3</pre>
```

base2int 29

```
seq <- c("ACCTCA")
base2codon(x = seq)

## Load a DNAStringSet. A matrix of codons is returned
data("aln", package = "GenomAutomorphism")
base2codon(x = aln)</pre>
```

base2int

Replace bases with integers from Z4 and Z5

# Description

A simple function to represent DNA bases as elements from the Abelian group of integers modulo 4 (Z4), 5 (Z5), or 2 (Z2).

#### Usage

```
base2int(base, ...)
## S4 method for signature 'character'
base2int(
  base,
  group = c("Z4", "Z5", "Z64", "Z125", "Z4^3", "Z5^3", "Z2"),
 cube = c("ACGT", "AGCT", "TCGA", "TGCA", "CATG", "GTAC", "CTAG", "GATC", "ACTG",
   "ATCG", "GTCA", "GCTA", "CAGT", "TAGC", "TGAC", "CGAT", "AGTC", "ATGC", "CGTA",
    "CTGA", "GACT", "GCAT", "TACG", "TCAG"),
  phychem = list(A = NULL, T = NULL, C = NULL, G = NULL, N = NULL)
)
## S4 method for signature 'data.frame'
base2int(
  base,
  group = c("Z4", "Z5", "Z64", "Z125", "Z4^3", "Z5^3", "Z2"),
 cube = c("ACGT", "AGCT", "TCGA", "TGCA", "CATG", "GTAC", "CTAG", "GATC", "ACTG",
   "ATCG", "GTCA", "GCTA", "CAGT", "TAGC", "TGAC", "CGAT", "AGTC", "ATGC", "CGTA",
    "CTGA", "GACT", "GCAT", "TACG", "TCAG"),
  phychem = list(A = NULL, T = NULL, C = NULL, G = NULL, N = NULL)
)
```

#### Arguments

A character vector, string , or a dataframe of letters from the DNA/RNA alphabet.

... Not in use.

group A character string denoting the group representation for the given base or codon as shown in reference (2-3).

30 base2int

cube

A character string denoting one of the 24 Genetic-code cubes, as given in references (2-3).

phychem

Optional. Eventually, it could be useful to represent DNA bases by numerical values of measured physicochemical properties. If provided, then this argument must be a named numerical list. For example, the scale values of deoxyribonucleic acids proton affinity (available at https://www.wolframalpha.com/ and in cell phone app: Wolfram Alpha):

list('A' = 0.87, 'C' = 0.88, 'T' = 0.82, 'G' = 0.89, 'N' = NA)

where symbol 'N' provide the value for any letter out of DNA base alphabet. In this example, we could write NA or 0 (see example section).

#### **Details**

For Z2 (binary representation of DNA bases), the cube bases are represented in their order by: '00', '01', '10', and '11' (examples section).

#### Value

A numerical vector.

base\_coord

DNA Sequences Methods

## **Description**

## Base coordinates on a given Abelian group representation:

Given a string denoting a codon or base from the DNA (or RNA) alphabet, function *base\_coord* return the base coordinates in the specify genetic-code Abelian group, as given in reference (1).

#### DNA sequences to GRanges of bases.:

Function *seq2granges* transform an object from DNAStringSet, DNAMultipleAlignment-class or a character into an object from BaseSeq.

#### BaseSeq-class object to DNAStringSet-class object.:

Function base\_seq2string\_set transforms an object from BaseSeq into an object from DNAStringSet-class.

## Usage

```
base_coord(base = NULL, filepath = NULL, cube = "ACGT", group = "Z4", ...)

## S4 method for signature 'DNAStringSet_OR_NULL'
base_coord(
  base = NULL,
  filepath = NULL,
  cube = c("ACGT", "AGCT", "TCGA", "TGCA", "CATG", "GTAC", "CTAG", "GATC", "ACTG",
    "ATCG", "GTCA", "GCTA", "CAGT", "TAGC", "TGAC", "CGAT", "AGTC", "ATGC", "CGTA",
    "CTGA", "GACT", "GCAT", "TACG", "TCAG"),
  group = c("Z4", "Z5"),
```

```
start = NA,

  start = NA,
  end = NA,
  chr = 1L,
  strand = "+",
  seq_alias = NULL,
)
base_seq2string_set(x, ...)
## S4 method for signature 'BaseSeq'
base_seq2string_set(x)
base_matrix(base, ...)
## S4 method for signature 'DNAStringSet_OR_NULL'
base_matrix(
  base,
 cube = c("ACGT", "AGCT", "TCGA", "TGCA", "CATG", "GTAC", "CTAG", "GATC", "ACTG", "ATCG", "GCTA", "CAGT", "TAGC", "TGAC", "CGAT", "AGTC", "ATGC", "CGTA",
    "CTGA", "GACT", "GCAT", "TACG", "TCAG"),
  group = c("Z4", "Z5"),
  seq_alias = NULL
)
```

## **Arguments**

base	An object from a DNAStringSet or DNAMultipleAlignment class carrying the DNA pairwise alignment of two sequences.
filepath	A character vector containing the path to a file in <b>fasta</b> format to be read. This argument must be given if <i>codon &amp; base</i> arguments are not provided.
cube	A character string denoting one of the 24 Genetic-code cubes, as given in references (2 2 3).
group	A character string denoting the group representation for the given base or codon as shown in reference (1).
	Not in use yet.

start, end, chr, strand

Optional parameters required to build a GRanges-class. If not provided the

default values given for the function definition will be used.

seq\_alias DNA sequence alias/ID and description.

x A 'BaseSeq' class object.

#### **Details**

#### Function 'base\_coord':

Function *base\_coord* is defined only for pairwise aligned sequences. Symbols "-" and "N" usually found in DNA sequence alignments to denote gaps and missing/unknown bases are represented by the number: '-1' on Z4 and '0' on Z5. In Z64 the symbol 'NA' will be returned for codons including symbols "-" and "N".

## Functions 'seq2granges' and 'base\_seq2string\_set':

For the sake of brevity the metacolumns from the object returned by function 'seq2granges' are named as 'S1', 'S2', 'S3', and so on. The original DNA sequence alias are stored in the slot named 'seq\_alias'. (see examples).

#### Value

Depending on the function called, different object will be returned:

## Function 'base\_coord':

This function returns a BaseGroup object carrying the DNA sequence(s) and their respective coordinates in the requested Abelian group of base representation (one-dimension, "Z4" or "Z5"). Observe that to get coordinates in the set of of integer numbers ("Z") is also possible but they are not defined to integrate a Abelian group. These are just used for the further insertion the codon set in the 3D space (R^3).

# Function 'seq2granges':

This function returns a BaseGroup object carrying the DNA sequence(s), one base per ranges. A BaseGroup class object inherits from GRanges-class.

#### Function 'base\_seq2string\_set':

This function returns a DNAStringSet-class.

A BaseGroup-class object.

brca1_aln2	Multiple Sequence Alignment (MSA) of Primate BRCA1 DNA repair
	genes.

# Description

This is a DNAMultipleAlignment carrying a MSA of BRCA1 DNA repair genes to be used in the examples provided for the package functions. The original file can be downloaded from GitHub at: https://bit.ly/3DimROD. This data set has 41 DNA sequences and it contains the previous 20 primate variants found in 'brca1\_aln' data set plus 21 single mutation variants (SMV) from the human sequence NM\_007298 transcript variant 4. The location of each SMV is given in the heading from each sequence.

## Usage

```
data("brca1_aln2", package = "GenomAutomorphism")
```

brca1\_autm2

Automorphisms between DNA Sequences from Primate BRCA1 Genes

### **Description**

This is a AutomorphismList object carrying a list of pairwise automorphisms between the DNA sequences from the MSA of primate BRCA1 DNA repair gene. The data set brca1\_aln2 has 41 DNA sequences and it contains the previous 20 primate variants found in 'braca1\_aln' data set plus 21 single mutation variants (SMV) from the human sequence NM\_007298 transcript variant 4. The location of each SMV is given in the heading from each sequence. The automorphisms were estimated from the brca1\_aln MSA with function autZ64.

### Usage

```
data("brca1_autm2", package = "GenomAutomorphism")
```

### **Format**

AutomorphismList class object.

38 codon\_coord

cdm\_z64

Codon Distance Matrices for the Standard Genetic Code on Z4

# **Description**

This is a list of 24 codon distance matrices created with function codon\_dist\_matrix in the set of 24 genetic-code cubes on Z4 (using the default weights and assuming the standard genetic code (SGC). The data set is created to speed up the computation when working with DNA sequences from superior organisms. Since distance matrices are symmetric, it is enough to provide the lower matrix. Each matrix is given as named/labeled vector (see the example).

## Usage

```
data("cdm_z64", package = "GenomAutomorphism")
```

#### **Format**

A list object.

### **Examples**

```
## Load the data set
data("cdm_z64", package = "GenomAutomorphism")
cdm_z64

## The lower matrix (given as vector) for cube "TCGA" (picking out the 20
## first values). Observe that this vector is labeled. Each numerical value
## corresponds to the distance between the codons specified by the
## name/label on it. For example, the distance between codons TTT and TCT
## is: 0.0625.
head(cdm_z64[[ "TCGA" ]], 20)
```

codon\_coord

Codon coordinates on a given a given Abelian group representation.

### **Description**

Given a string denoting a codon or base from the DNA (or RNA) alphabet and a genetic-code Abelian group as given in reference (1).

codon\_coord 39

#### Usage

```
codon_coord(codon = NULL, ...)
## S4 method for signature 'BaseGroup'
codon_coord(codon, group = NULL)
## S4 method for signature 'DNAStringSet_OR_NULL'
codon_coord(
  codon = NULL,
  filepath = NULL,
 cube = c("ACGT", "AGCT", "TCGA", "TGCA", "CATG", "GTAC", "CTAG", "GATC", "ACTG",
   "ATCG", "GTCA", "GCTA", "CAGT", "TAGC", "TGAC", "CGAT", "AGTC", "ATGC", "CGTA",
     "CTGA", "GACT", "GCAT", "TACG", "TCAG"),
  group = c("Z4", "Z5", "Z64", "Z125", "Z4^3", "Z5^3"),
  start = NA,
  end = NA,
  chr = 1L,
  strand = "+"
)
## S4 method for signature 'matrix_OR_data_frame'
codon_coord(
  codon,
 cube = c("ACGT", "AGCT", "TCGA", "TGCA", "CATG", "GTAC", "CTAG", "GATC", "ACTG",
   "ATCG", "GTCA", "GCTA", "CAGT", "TAGC", "TGAC", "CGAT", "AGTC", "ATGC", "CGTA",
    "CTGA", "GACT", "GCAT", "TACG", "TCAG"),
  group = c("Z64", "Z125", "Z4^3", "Z5^3")
)
```

### Arguments

codon An object from BaseGroup-class (generated with function base\_coord), DNAStringSet

or from DNAMultipleAlignment class carrying the DNA pairwise alignment of

two sequences.

... Not in use.

group A character string denoting the group representation for the given base or codon

as shown in reference (2-3).

filepath A character vector containing the path to a file in **fasta** format to be read. This

argument must be given if *codon & base* arguments are not provided.

cube A character string denoting one of the 24 Genetic-code cubes, as given in refer-

ences (2-3).

start, end, chr, strand

Optional parameters required to build a GRanges-class. If not provided the default values given for the function definition will be used.

40 codon\_coord

#### **Details**

Symbols "-" and "N" usually found in DNA sequence alignments to denote gaps and missing/unknown bases are represented by the number: '-1' on Z4 and '0' on Z5. In Z64 the symbol 'NA' will be returned for codons including symbols "-" and "N".

This function returns a GRanges-class object carrying the codon sequence(s) and their respective coordinates in the requested Abelian group or simply, when  $group = 'Z5^3'$  3D-coordinates, which are derive from Z5 as indicated in reference (3). Notice that the coordinates can be 3D or just one-dimension ("Z64" or "Z125"). Hence, the pairwise alignment provided in argument **codon** must correspond to codon sequences.

#### Value

A CodonGroup-class object.

codon\_dist

Weighted Manhattan Distance Between Codons

### **Description**

This function computes the weighted Manhattan distance between codons from two sequences as given in reference (1). That is, given two codons x and y with coordinates on the set of integers modulo 5 ("Z5"):  $x = (x_1, x_2, x_3)$  and  $x = (y_1, y_2, y_3)$  (see (1)), the Weighted Manhattan distance between this two codons is defined as:

$$d_w(x,y) = |x_1 - y_1|/5 + |x_2 - y_2| + |x_3 - y_3|/25$$

If the codon coordinates are given on "Z4", then the Weighted Manhattan distance is define as:

$$d_w(x,y) = |x_1 - y_1|/4 + |x_2 - y_2| + |x_3 - y_3|/16$$

Herein, we move to the generalized version given in reference (3), for which:

$$d_w(x,y) = |x_1 - y_1|w_1 + |x_2 - y_2|w_2 + |x_3 - y_3|w_3$$

where we use the vector of  $weight = (w_1, w_2, w_3)$ .

### Usage

```
codon_dist(x, y, ...)
## S4 method for signature 'DNAStringSet'
codon_dist(
    x,
    weight = NULL,
    group = c("Z4", "Z5"),
    cube = c("ACGT", "AGCT", "TCGA", "TGCA", "CATG", "GTAC", "CTAG", "GATC", "ACTG",
    "ATCG", "GTCA", "GCTA", "CAGT", "TAGC", "TGAC", "CGAT", "AGTC", "ATGC", "CGTA",
    "CTGA", "GACT", "GCAT", "TACG", "TCAG"),
    num.cores = 1L,
    tasks = 0L,
```

42 codon\_dist

```
verbose = FALSE
)
## S4 method for signature 'character'
codon_dist(
  х,
 у,
 weight = NULL,
  group = c("Z4", "Z5"),
 cube = c("ACGT", "AGCT", "TCGA", "TGCA", "CATG", "GTAC", "CTAG", "GATC", "ACTG",
   "ATCG", "GTCA", "GCTA", "CAGT", "TAGC", "TGAC", "CGAT", "AGTC", "ATGC", "CGTA",
    "CTGA", "GACT", "GCAT", "TACG", "TCAG"),
  num.cores = 1L,
  tasks = 0L,
  verbose = FALSE
)
## S4 method for signature 'CodonGroup_OR_Automorphisms'
codon_dist(
  х,
 weight = NULL,
 group = c("Z4", "Z5"),
 cube = c("ACGT", "AGCT", "TCGA", "TGCA", "CATG", "GTAC", "CTAG", "GATC", "ACTG",
   "ATCG", "GTCA", "GCTA", "CAGT", "TAGC", "TGAC", "CGAT", "AGTC", "ATGC", "CGTA",
    "CTGA", "GACT", "GCAT", "TACG", "TCAG"),
  num.cores = 1L,
  tasks = 0L,
  verbose = FALSE
)
```

### Arguments

x, y A character string of codon sequences, i.e., sequences of DNA base-triplets. If only 'x' argument is given, then it must be a DNAStringSet-class object.

... Not in use yet.

weight A numerical vector of weights to compute weighted Manhattan distance between codons. If weight = NULL, then weight = (1/4, 1, 1/16) for group = 1/4

"Z4" and weight = (1/5, 1, 1/25) for group = "Z5".

group A character string denoting the group representation for the given codon se-

quence as shown in reference (2-3).

cube A character string denoting one of the 24 Genetic-code cubes, as given in refer-

ences (2-3).

num.cores, tasks

Parameters for parallel computation using package BiocParallel-package: the number of cores to use, i.e. at most how many child processes will be run simultaneously (see bplapply and the number of tasks per job (only for Linux

OS).

verbose If TRUE, prints the progress bar.

codon\_dist 43

#### Value

A numerical vector with the pairwise distances between codons in sequences 'x' and 'y'.

44 codon\_dist\_matrix

codon\_dist\_matrix

Compute Codon Distance Matrix

### **Description**

This function computes the codon distance matrix based on the weighted Manhattan distance between codons estimated with function codon\_dist.

# Usage

```
codon_dist_matrix(
  genetic_code = "1",
  group = c("Z4", "Z5"),
  weight = NULL,
  cube = c("ACGT", "AGCT", "TCGA", "TGCA", "CATG", "GTAC", "CTAG", "GATC", "ACTG",
    "ATCG", "GTCA", "GCTA", "CAGT", "TAGC", "TGAC", "CGAT", "AGTC", "ATGC", "CGTA",
    "CTGA", "GACT", "GCAT", "TACG", "TCAG"),
  output = c("list", "vector", "dist"),
  num.cores = 1L
)
```

### **Arguments**

genetic_code	A single string that uniquely identifies the genetic code to extract. Should be one of the values in the id or name2 columns of GENETIC_CODE_TABLE.
group	A character string denoting the group representation for the given codon sequence as shown in reference (2-3).
weight	A numerical vector of weights to compute weighted Manhattan distance between codons. If $weight = NULL$ , then $weight = (1/4, 1, 1/16)$ for $group =$ "Z4" and $weight = (1/5, 1, 1/25)$ for $group =$ "Z5" (see codon_dist).
cube	A character string denoting one of the 24 Genetic-code cubes, as given in references (2-3).
output	Format of the returned lower triangular matrix: as a list of 63 elements (labeled) or as a labeled vector using codons as labels.
num.cores	An integer to setup the number of parallel workers via makeCluster.

### **Details**

By construction, a distance matrix is a symmetric matrix. Hence, the knowledge of lower triangular matrix is enough for its application to any downstream analysis.

#### Value

A lower triangular matrix excluding the diagonal.

codon\_matrix 45

#### See Also

```
codon_dist.
```

#### **Examples**

codon\_matrix

Codon Coordinate Matrix

### **Description**

This function build the coordinate matrix for each sequence from an aligned set of DNA codon sequences.

## Usage

```
codon_matrix(base, ...)
## S4 method for signature 'BaseSeqMatrix'
codon_matrix(base, num.cores = 1L, tasks = 0L, verbose = TRUE, ...)
## S4 method for signature 'DNAStringSet'

 cube = c("ACGT", "AGCT", "TCGA", "TGCA", "CATG", "GTAC", "CTAG", "GATC", "ACTG",
   "ATCG", "GTCA", "GCTA", "CAGT", "TAGC", "TGAC", "CGAT", "AGTC", "ATGC", "CGTA",
    "CTGA", "GACT", "GCAT", "TACG", "TCAG"),
  group = c("Z4", "Z5"),
  num.cores = 1L,
  tasks = 0L,
  verbose = TRUE
)
## S4 method for signature 'DNAMultipleAlignment'
codon_matrix(
  base,
 cube = c("ACGT", "AGCT", "TCGA", "TGCA", "CATG", "GTAC", "CTAG", "GATC", "ACTG",
   "ATCG", "GTCA", "GCTA", "CAGT", "TAGC", "TGAC", "CGAT", "AGTC", "ATGC", "CGTA",
    "CTGA", "GACT", "GCAT", "TACG", "TCAG"),
```

46 codon\_matrix

```
group = c("Z4", "Z5"),
num.cores = 1L,
tasks = 0L,
verbose = TRUE
)
```

### **Arguments**

base A DNAMultipleAlignment, a DNAStringSet, or a BaseSeqMatrix.

... Not in use yet.

num.cores, tasks

Parameters for parallel computation using package BiocParallel-package: the number of cores to use, i.e. at most how many child processes will be run simultaneously (see bplapply and the number of tasks per job (only for Linux

OS).

verbose If TRUE, prints the function log to stdout

cube A character string denoting one of the 24 Genetic-code cubes, as given in refer-

ences (3-4).

group A character string denoting the group representation for the given base or codon

as shown in reference (3-4).

#### **Details**

The purpose of this function is making the codon coordinates from multiple sequence alignments (MSA) available for further downstream statistical analyses, like those reported in references (1) and (2).

#### Value

A ListCodonMatrix class object with the codon coordinate on its metacolumns.

  output = c("all_pairs", "unique_pairs", "unique")
)
```

# Arguments

x A Automorphism-class, a AutomorphismList-class, a AutomorphismByCoef

or a  ${\tt AutomorphismByCoefList}$  class object.

... Not in use.

conserved Logical, Whether to return the *conserved* or the *non-conserved regions*.

output A character string. Type of output.

num.cores, tasks

Integers. Argument *num.cores* denotes the number of cores to use, i.e. at most how many child processes will be run simultaneously (see bplapply function from BiocParallel package). Argument *tasks* denotes the number of tasks per job. value must be a scalar integer >= 0L. In this documentation a job is defined as a single call to a function, such as bplapply. A task is the division of the X argument into chunks. When tasks == 0 (default), X is divided as evenly as possible over the number of workers (see MulticoreParam from BiocParallel

package).

verbose logic(1). If TRUE, enable progress bar.

#### Value

A AutomorphismByCoef class object containing the requested regions.

```
## Load dataset
data("autm", package = "GenomAutomorphism")
conserved_regions(autm[1:3])
```

covid\_aln 49

```
## Load automorphism found COVID datatset

dna\_phyche

Some Physicochemical Properties of DNA bases

# Description

This data set carries some relevant physicochemical properties of the DNA bases. Available properties are:

- "proton\_affinity: " It is an indicatio of the thermodynamic gradient between a molecule and the anionic form of that molecule upon removal of a proton from it (Wikipedia). The proton affinity values, given in kJ/mol, were taken from reference (1), also available in Wolfram Alpha at https://www.wolframalpha.com/ and in the cell phone App 'Wolfram Alpha'.. Reference (2) provides several measurements accomplished by several computational and experimental approaches.
- "partition\_coef: " 1-octanol/water partition coefficients, logP. In the physical sciences, a partition coefficient (P) or distribution coefficient (D) is the ratio of concentrations of a compound in a mixture of two immiscible solvents at equilibrium (3). The partition coefficient measures how hydrophilic ("water-loving") or hydrophobic ("water-fearing") a chemical substance is. Partition coefficients are useful in estimating the distribution of drugs within the body. Hydrophobic drugs with high octanol-water partition coefficients are mainly distributed to hydrophobic areas such as lipid bilayers of cells. Conversely, hydrophilic drugs (low octanol/water partition coefficients) are found primarily in aqueous regions such as blood serum. The partition coefficient values included here were taken from reference (1), also available in Wolfram Alpha at https://www.wolframalpha.com/ and in the cell phone App 'Wolfram Alpha'.
- "dipole\_moment: " Dipole-dipole, dipole-induced-dipole and London force interactions among the bases in the helix are large, and make the free energy of the helix depend on the base composition and sequence. The dipole moment values were taken from reference (4). The dipole moment of DNA bases refers to the measure of polarity in the chemical bonds between atoms within the nucleobases. Dipole moments arise due to differences in electronegativity between the bonded atoms. In DNA bases, these dipole moments can influence the orientation of the bases when interacting with other molecules or surfaces, such as graphene/h-BN interfaces. The concept of dipole moments has been applied to analyze the electric moments of RNA-binding proteins, which can help identify DNA-binding proteins and provide insights into their mechanisms and prediction.
- "tautomerization\_energy: " The term "tautomerism" is usually defined as structural isomerism with a low barrier to interconversion between the isomers, for example, the enol/imino forms for cytosine and guanine. Tautomerization is a process where the chemical structure of a molecule, such as DNA bases, undergoes a rearrangement of its atoms. This rearrangement results in the formation of different isomers, called tautomers, which can exist in solution or in a cell. The DNA bases can undergo tautomeric shifts, which can potentially contribute to mutagenic mispairings during DNA replication. The energy required for tautomerization of

dna\_phychem 53

DNA bases is known as tautomerization energy. These values were taken from reference (2) and the value for each base corresponds to the average of the values estimated from different measurement approaches.

### Usage

```
data("dna_phyche", package = "GenomAutomorphism")
```

#### **Format**

A data frame object.

### **Examples**

dna\_phychem

DNA numerical matrix

### **Description**

This function applies the numerical indices representing various physicochemical and biochemical properties of DNA bases. As results, DNA sequences are represented as numerical vectors which can be subject of further downstream statistical analysis and digital signal processing.

54 dna\_phychem

### Usage

```
dna_phychem(seqs, ...)
## S4 method for signature 'character'
dna_phychem(
    seqs,
    phychem = list(A = NULL, T = NULL, C = NULL, G = NULL, N = NULL)
)

## S4 method for signature 'DNAStringSet_OR_DNAMultipleAlignment'
dna_phychem(
    seqs,
    phychem = list(A = NULL, T = NULL, C = NULL, G = NULL, N = NULL),
    index_name = NULL,
    ...
)
```

### Arguments

seqs A character string, a DNAStringSet or a DNAMultipleAlignment class object

carrying the DNA pairwise alignment of two sequences.

... Not in use.

phychem A list of DNA bases physicochemical properties, e.g., like those provided in

dna\_phyche.

index\_name Optional. Name of breve description of the base physicochemical property ap-

plied to represent the DNA sequence.

#### Value

A MatrixSeq-class object.

getAutomorphisms

Get Automorphisms

# **Description**

For the sake of saving memory, each Automorphism-class objects is stored in an AutomorphismList-class, which does not inherits from a GRanges-class.

# Usage

```
getAutomorphisms(x, ...)
## S4 method for signature 'AutomorphismList'
getAutomorphisms(x)
## S4 method for signature 'list'
getAutomorphisms(x)
## S4 method for signature 'DataFrame_OR_data.frame'
getAutomorphisms(x)
```

### **Arguments**

```
x An AutomorphismList-class.
```

... Not in use.

#### **Details**

This function just transform each Automorphism-class object into an object from the same class but now inheriting from a GRanges-class.

#### Value

This function returns an AutomorphismList-class object as a list of Automorphism-class objects, which inherits from GRanges-class objects.

```
An AutomorphismList-class
An Automorphism-class
```

56 get\_coord

### **Examples**

```
## Load a dataset
data("autm", package = "GenomAutomorphism")
aut <- mcols(autm)
aut ## This a DataFrame object

## The natural ranges for the sequence (from 1 to length(aut)) are added
getAutomorphisms(aut)

## A list of automorphisms
aut <- list(aut, aut)
getAutomorphisms(aut)

## Automorphism-class inherits from 'GRanges-class'
aut <- as(autm, "GRanges")
as(aut, "Automorphism")</pre>
```

get\_coord

DNA base/codon sequence and coordinates represented on a given Abelian group.

### **Description**

Given a string denoting a codon or base from the DNA (or RNA) alphabet and a genetic-code Abelian group as given in reference (1), this function returns an object from CodonGroup-class carrying the DNA base/codon sequence and coordinates represented on the given Abelian group.

### Usage

```
get_coord(x, ...)
## S4 method for signature 'BaseGroup_OR_CodonGroup'
get_coord(x, output = c("all", "matrix.list"))
## S4 method for signature 'DNAStringSet_OR_NULL'
get_coord(
  Х,
  output = c("all", "matrix.list"),
  base_seq = TRUE,
  filepath = NULL,
  cube = "ACGT",
  group = "Z4",
  start = NA,
  end = NA,
  chr = 1L,
  strand = "+"
)
```

get\_coord 57

### **Arguments**

X	An object from a BaseGroup-class, CodonGroup-class, DNAStringSet or
	DNAMultipleAlignment class carrying the DNA pairwise alignment of two se-
	quences. Objects from BaseGroup-class and CodonGroup-class are gener-
	ated with functions: base_coord and codon_coord, respectively.
	Not in more

... Not in use.

output See 'Value' section.

base\_seq Logical. Whether to return the base or codon coordinates on the selected Abelian

group. If codon coordinates are requested, then the number of the DNA bases in

the given sequences must be multiple of 3.

filepath A character vector containing the path to a file in **fasta** format to be read. This

argument must be given if codon & base arguments are not provided.

cube A character string denoting one of the 24 Genetic-code cubes, as given in refer-

ences (2 2 3).

group A character string denoting the group representation for the given base or codon

as shown in reference (1).

start, end, chr, strand

Optional parameters required to build a GRanges-class. If not provided the default values given for the function definition will be used.

#### **Details**

Symbols '-' and 'N' usually found in DNA sequence alignments to denote gaps and missing/unknown bases are represented by the number: '-1' on Z4 and '0' in Z5. In Z64 the symbol 'NA' will be returned for codons including symbols '-' and 'N'.

Although the CodonGroup-class object returned by functions codon\_coord and base\_coord are useful to store genomic information, the base and codon coordinates are not given on them as numeric magnitudes. Function get\_coord provides the way to get the coordinates in a numeric object in object from and still to preserve the base/codon sequence information.

#### Value

An object from CodonGroup-class class is returned when output = 'all'. This has two slots, the first one carrying a list of matrices and the second one carrying the codon/base sequence information. That is, if x is an object from CodonGroup-class class, then a list of matrices of codon coordinate can be retrieved as x@CoordList and the information on the codon sequence as x@SeqRanges.

if *output* = 'matrix.list', then an object from MatrixList class is returned.

```
## Load a pairwise alignment
data("aln", package = "GenomAutomorphism")
aln
## DNA base representation in the Abelian group Z5
coord <- get_coord(</pre>
```

58 get\_mutscore

```
x = aln,
    cube = "ACGT",
    group = "Z5"
)
coord ## A list of vectors
## Extract the coordinate list
coordList(coord)
## Extract the sequence list
seqRanges(coord)
## DNA codon representation in the Abelian group Z64
coord <- get_coord(</pre>
    x = aln,
    base_seq = FALSE,
    cube = "ACGT",
    group = "Z64"
)
coord
## Extract the coordinate list
coordList(coord)
## Extract the sequence list
seqRanges(coord)
```

get\_mutscore

Get Mutation Score from an AAindex or a Mutation/Distance Matrix

# Description

This function is applied to get the mutation or contact potential scores representing the similarity/distance between amino acids corresponding to substitution mutations. The scores are retrieved from a mutation matrix or a statistical protein contact potentials matrix from AAindex (ver.9.2).

Alternatively, the mutation scores can be estimated based on an user mutation matrix, for example, see aminoacid\_dist and codon\_dist\_matrix.

# Usage

```
get_mutscore(aa1, aa2, ...)
## S4 method for signature 'character, character'
get_mutscore(
    aa1,
    aa2,
    acc = NULL,
    aaindex = NULL,
```

get\_mutscore 59

```
mutmat = NULL,
  alphabet = c("AA", "DNA"),
 num.cores = 1L,
  tasks = 0L,
  verbose = FALSE,
)
## S4 method for signature 'BaseSeq,missing'
get_mutscore(
  aa1,
  aa2,
  acc = NULL,
  aaindex = NULL,
 mutmat = NULL,
  alphabet = c("AA", "DNA"),
  stat = mean,
  numcores = 1L,
  num.cores = 1L,
  tasks = 0L,
  output = c("dist", "matrix", "vector"),
 na.rm = TRUE,
 verbose = TRUE,
  . . .
)
## S4 method for signature 'DNAStringSet,missing'
get_mutscore(
 aa1,
  aa2,
  acc = NULL,
  aaindex = NULL,
 mutmat = NULL,
  alphabet = c("AA", "DNA"),
  stat = mean,
 num.cores = 1L,
  tasks = 0L,
  verbose = TRUE,
  output = c("dist", "matrix", "vector"),
 na.rm = TRUE,
)
## S4 method for signature 'DNAMultipleAlignment, missing'
get_mutscore(
 aa1,
  aa2,
  acc = NULL,
```

60 get\_mutscore

```
aaindex = NULL,
mutmat = NULL,
alphabet = c("AA", "DNA"),
stat = mean,
num.cores = 1L,
tasks = 0L,
verbose = TRUE,
output = c("dist", "matrix", "vector"),
na.rm = TRUE,
...
)
```

### **Arguments**

aa1, aa2 A simple character representing an amino acids or a character string of let-

ter from the amino acid alphabet or base-triplets from the DNA/RNA alphabet. If *aa1* is an object from any of the classes: BaseSeq, DNAStringSet, or

DNAMultipleAlignment, then argument *aa2* is not required.

... Not in use.

acc Accession id for a specified mutation or contact potential matrix.

aaindex Database where the requested accession id is locate. The possible values are:

"aaindex2" or "aaindex3".

mutmat A mutation or any score matrix provided by the user.

alphabet Whether the alphabet is from the 20 amino acid (AA) or four (DNA)/RNA base

alphabet. This would prevent mistakes, i.e., the strings "ACG" would be a base-triplet on the DNA alphabet or simply the amino acid sequence of alanine, cys-

teine, and glutamic acid.

num.cores, tasks

Parameters for parallel computation using package BiocParallel-package: the number of cores to use, i.e. at most how many child processes will be run simultaneously (see bplapply and the number of tasks per job (only for Linux

OS).

verbose Optional. Only if num.cores > 1. If TRUE, prints the function log to stdout.

stat Statistic that will be used to summarize the scores of the DNA sequences pro-

vided. Only if aa1 is an object from any of the classes: BaseSeq, DNAStringSet,

or DNAMultipleAlignment.

numcores An integer to setup the number of parallel workers via makeCluster.

output Optional. Class of the returned object. Only if *aa1* is an object from any of the

classes: BaseSeq, DNAStringSet, or DNAMultipleAlignment.

na.rm a logical evaluating to TRUE or FALSE indicating whether NA values should

be stripped before the computation proceeds.

#### Details

If a score matrix is provided by the user, then it must be a symmetric matrix 20x20.

matrices 61

#### Value

A single numeric score or a numerical vector, or if *aa1* is an object from any of the classes: BaseSeq, DNAStringSet, or DNAMultipleAlignment, then depending on the user selection the returned object will be:

- 1. A lower diagonal numerical vector of the sequence pairwise scores.
- 2. A dist-class object.
- 3. A whole score matrix.

### **Examples**

matrices

Get the Coordinate Representation from DNA Sequences on Specified Abelian Group

### **Description**

Extract the Coordinate Representation from DNA Sequences on Specified Abelian Group.

62 matrices

### Usage

```
matrices(x, ...)
## S4 method for signature 'MatrixList'
matrices(x)
## S4 method for signature 'CodonSeq'
matrices(x)
## S4 method for signature 'DNAStringSet_OR_NULL'
matrices(
  Χ,
  base_seq = TRUE,
  filepath = NULL,
  cube = "ACGT",
  group = c("Z4", "Z5", "Z64", "Z125", "Z4^3", "Z5^3"),
  start = NA,
  end = NA,
  chr = 1L,
  strand = "+"
)
```

### **Arguments**

cube

X	An object from a DNAStringSet or DNAMultipleAlignment class carrying the
	DNA pairwise alignment of two sequences.
	Not in use.
base_seq	Logical. Whether to return the base or codon coordinates on the selected Abelian

group. If codon coordinates are requested, then the number of the DNA bases in the given sequences must be multiple of 3.

A character vector containing the path to a file in **fasta** format to be read. This argument must be given if *codon & base* arguments are not provided.

A character string denoting one of the 24 Genetic-code cubes, as given in refer-

ences (2-3).

group A character string denoting the group representation for the given base or codon

as shown in reference (1).

start, end, chr, strand

Optional parameters required to build a GRanges-class. If not provided the default values given for the function definition will be used.

### **Details**

These are alternative ways to get the list of matrices of base/codon coordinate and the information on the codon sequence from CodonSeq and MatrixList class objects. These functions can either take the output from functions base\_coord and matrices or to operate directly on a DNAStringSet or to retrieve the a DNA sequence alignment from a file.

matrices 63

**base\_seq** parameter will determine whether to return the matrices of coordinate for a DNA or codon sequence. While in function seqranges, **granges** parameter will determine whether to return a GRanges-class object or a DataFrame.

#### Value

The a list of vectors (group = c("Z4", "Z5", "Z64", "Z125") or a list of matrices (group =  $("Z4^3", "Z5^3")$ ) carrying the coordinate representation on the specified Abelian group.

64 mod

)

mod

Modulo Operation

### **Description**

Integer remainder of the division of the integer n by m: n mod m.

### Usage

```
mod(n, m, ...)
## S4 method for signature 'matrix,numeric'
mod(n, m)
```

# Arguments

n A numeric vector (preferably of integers), a matrix where each element can be reduced to integers.

m An integer vector (positive, zero, or negative).

... Not in use.

### Value

An element of x, an Automorphism-class object.

### Author(s)

Robersy Sanchez (https://genomaths.com).

```
## Example 1
## Build a matrix 'n' and set a vector of integers 'm'
n <- diag(x=1, nrow = 4, ncol = 4) * c(43,125,2,112)
m <- c(64,4,4,64)

## Operation n mod m
mod(n = n, m = m)

## Or simply:
n %% m

## Example 2
m <- matrix(c(8,2,3, 11,12,13), nrow = 2)
m
m %% 4</pre>
```

modlineq 65

modlineq

Modular System of Linear Equation Solver (MLE)

## **Description**

If a, b, and c are integer vectors, this function try to find, at each coordinate, the solution of the MLE  $ax = b \mod n$ . If the MLE  $ax = b \mod n$  has not solutions (see modlin), the value reported for the coordinate will be 0 and the corresponding translation.

### Usage

```
modlineq(a, b, n, no.sol = 0L)
```

### **Arguments**

а	An integer or a vector of integers.
b	An integer or a vector of integers.
n	An integer or a vector of integers.
no.sol	Values to return when the equation is not solvable or yield the value 0. Default is 0.

### **Details**

For a, b, and c integer scalars, it is just a wrapper function to call modlin.

#### Value

If the solution is exact, then a numerical vector will be returned, otherwise, if there is not exact solution for some coordinate, the a list carrying the element on the diagonal matrix and a translation vector will be returned.

```
## Set the vector x, y, and m.
x <- c(9,32,24,56,60,27,28,5)
y <- c(8,1,0,56,60,0,28,2)
modulo <- c(64,125,64,64,64,64,64)
## Try to solve the modular equation a x = b mod n
m <- modlineq(a = x, b = y, n = modulo)
m

## Or in matrix form
diag(m)
## The reverse mapping is an affine transformation
mt <- modlineq(a = y, b = x, n = modulo, no.sol = 1L)
mt</pre>
```

66 mut\_type

```
## That is, vector 'x' is revovered with the transformation
(y %*% diag(mt$diag) + mt$translation) %% modulo

# Or
cat("\n----\n")
(y %*% diag(mt$diag) + mt$translation) %% modulo == x
```

mut\_type

Classification of DNA base mutations

### **Description**

Each DNA/RNA base can be classified into three main classes according to three criteria (1): number of hydrogen bonds (strong-weak), chemical type (purine-pyrimidine), and chemical groups (amino versus keto). Each criterion produces a partition of the set of bases: 1) According to the number of hydrogen bonds (on DNA/RNA double helix): strong S=(C,G) (three hydrogen bonds) and weak W=(A,U) (two hydrogen bonds). According to the chemical type: purines R=(A,G) and pyrimidines Y=(C,U). 3). According to the presence of amino or keto groups on the base rings: amino M=(C,A) and keto K=(G,U). So, each mutational event can be classified as according to the type of involved in it (2).

### Usage

```
mut_type(x, y)
```

# **Arguments**

x, y

Character strings denoting DNA bases

### Value

A character string of same length of 'x' and 'y'.

peptide\_phychem\_index Amino acid numerical matrix

### **Description**

This function applies numerical indices representing various physicochemical and biochemical properties of amino acids and pairs of amino acids to DNA protein-coding or to aminoacid sequences. As results, DNA protein-coding or the aminoacid sequences are represented as numerical vectors which can be subject of further downstream statistical analysis and digital signal processing.

# Usage

```
peptide_phychem_index(aa, ...)
## S4 method for signature 'character'
peptide_phychem_index(
  aa,
  acc = NULL.
  aaindex = NA,
  userindex = NULL,
  alphabet = c("AA", "DNA"),
  genetic.code = getGeneticCode("1"),
  no.init.codon = FALSE,
  if.fuzzy.codon = "error",
  . . .
)
## S4 method for signature 'DNAStringSet_OR_DNAMultipleAlignment'
peptide_phychem_index(
  aa,
  acc = NULL,
  aaindex = NA,
  userindex = NULL,
  alphabet = c("AA", "DNA"),
```

```
genetic.code = getGeneticCode("1"),
  no.init.codon = FALSE,
  if.fuzzy.codon = "error",
  num.cores = 1L,
  tasks = 0L,
  verbose = FALSE,
)
```

# Arguments aa

carrying the DNA pairwise alignment of two sequences. Not in use. Accession id for a specified mutation or contact potential matrix. acc Database where the requested accession id is locate and from where the aminoacid aaindex indices can be obtained. The possible values are: "aaindex2" or "aaindex3". User provided aminoacid indices. This can be a numerical vector or a matrix userindex (20 x 20). If a numerical matrix is provided, then the aminoacid indices are computes as column averages. alphabet Whether the alphabet is from the 20 aminoacid (AA) or four (DNA)/RNA base alphabet. This would prevent mistakes, i.e., the strings "ACG" would be a basetriplet on the DNA alphabet or simply the amino acid sequence of alanine, cysteine, and glutamic acid. genetic.code, no.init.codon, if.fuzzy.codon The same as given in function translation.

num.cores, tasks

Parameters for parallel computation using package BiocParallel-package: the number of cores to use, i.e. at most how many child processes will be run simultaneously (see bplapply and the number of tasks per job (only for Linux

A character string, a DNAStringSet or a DNAMultipleAlignment class object

OS).

verbose If TRUE, prints the function log to stdout.

### **Details**

If a DNA sequence is given, then it is assumed that it is a DNA base-triplet sequence, i.e., the base sequence must be multiple of 3.

Errors can be originated if the given sequences carry letter which are not from the DNA or aminoacid alphabet.

### Value

Depending on the user specifications, a mutation or contact potential matrix, a list of available matrices (indices) ids or index names can be returned. More specifically:

aa\_mutmat: Returns an aminoacid mutation matrix or a statistical protein contact potentials ma-

**aa\_index:** Returns the specified aminoacid physicochemical indices.

seqranges 69

### Author(s)

Robersy Sanchez https://genomaths.com

### **Examples**

segranges

Get DNA sequence Ranges and Coordinates representation on a given Abelian Group

### **Description**

Extract the gene ranges and coordinates from a pairwise alignment of codon/base sequences represented on a given Abelian group.

### Usage

```
seqranges(x, ...)
## S4 method for signature 'CodonSeq'
seqranges(x, granges = TRUE)
## S4 method for signature 'DNAStringSet_OR_NULL'
seqranges(
    x,

70 seqranges

```
base_seq = TRUE,
filepath = NULL,
start = NA,
end = NA,
chr = 1L,
strand = "+"
```

### **Arguments**

x An object from a DNAStringSet or DNAMultipleAlignment class carrying the

DNA pairwise alignment of two sequences.

... Not in use.

granges Logical. Whether to return a GRanges-class object or a DataFrame.

base\_seq Logical. Whether to return the base or codon coordinates on the selected Abelian

group. If codon coordinates are requested, then the number of the DNA bases in

the given sequences must be multiple of 3.

filepath A character vector containing the path to a file in **fasta** format to be read. This

argument must be given if codon & base arguments are not provided.

start, end, chr, strand

Optional parameters required to build a GRanges-class. If not provided the

default values given for the function definition will be used.

### **Details**

This function provide an alternative way to get the codon coordinate and the information on the codon sequence from a CodonSeq class objects. The function can either take the output from functions codon\_coord or to operate directly on a DNAStringSet or to retrieve the a DNA sequence alignment from a file.

## Value

```
A GRanges-class
```

matrices, codon\_coord, and base\_coord.

### **Examples**

```
## Load a pairwise alignment
data("aln", package = "GenomAutomorphism")
aln

## A GRanges object carrying the aligned DNA sequence.
seqranges(
    x = aln,
    base_seq = TRUE,
    filepath = NULL,
)

## A GRanges object carrying the aligned codon sequence.
seqranges(
    x = aln,
    base_seq = FALSE,
    filepath = NULL,
)
```

slapply

Apply a function over a list-like object preserving its attributes

### Description

This function apply a function over a list-like object preserving its attributes and simplify (if requested) the list as sapply function does. **slapply** returns a list of the same length as 'x', each element of which is the result of applying FUN to the corresponding element of 'x'.

### Usage

```
slapply(
    x,
    FUN,
    keep.attr = FALSE,
    class = NULL,
    simplify = TRUE,
    USE.NAMES = TRUE,
    ...
)
```

# **Arguments**

```
x A list-like or vector-like object.FUN, ... The same as described in lapply.
```

```
keep.attr Logic. If TRUE, then the original attributes from 'x' are preserved in the returned list. Default is FALSE.

class Name of the class to which the returned list belongs to. Default is NULL. simplify, USE.NAMES

The same as described in sapply.
```

### Value

Same as in ?base::lapply if keep.attr = FALSE. Otherwise same values preserving original attributes from 'x'.

#### Author(s)

```
Robersy Sanchez (https://genomaths.com).
```

### See Also

```
lapply and sapply
```

### **Examples**

```
sortByChromAndStart Sorting GRanges-class \ objects
```

### **Description**

Sorts a GRanges-class objects by seqname (chromosome), start, and position.

### Usage

```
sortByChromAndStart(x)
sortByChromAndEnd(x)
```

str2chr 73

### **Arguments**

Χ

GRanges object

#### **Details**

Objects that inherits from a GRanges-class can be sorted as well.

### Value

GRanges-class object or from the original object class.

### **Examples**

```
GR \leftarrow as(c("chr2:1-1", "chr1:1-1"), "GRanges") GR \leftarrow sortByChromAndStart(GR)
```

str2chr

String to Character

### **Description**

A simple function to transform a string into character vector.

### Usage

```
str2chr(x, split = "", ...)
## S4 method for signature 'character'
str2chr(x, split = "", ...)
## S4 method for signature 'list'
str2chr(x, split = "", num.cores = 1L, tasks = 0L, verbose = FALSE, ...)
```

#### **Arguments**

x A character string or a list/vector of character strings.

split The same as in strsplit

... Further parameters for strsplit.

num.cores, tasks

Parameters for parallel computation using package BiocParallel-package: the number of cores to use, i.e. at most how many child processes will be run simultaneously (see bplapply and the number of tasks per job (only for Linux OC)

OS).

verbose If TRUE, prints the function log to stdout.

74 str2dig

### Value

A character string

#### Author(s)

Robersy Sanchez https://genomaths.com

### **Examples**

```
## A character string
str2chr("ATCAGCGGGATCTT")

## A list of character strings
str2chr(list(str1 = "ATCAGCGGGATCTT", str2 = "CTTCTTCGTCAGGC"))
```

str2dig

String to Digits

### **Description**

A simple function to transform a string of digits into a numeric vector.

### Usage

```
str2dig(x, split = "", ...)
## S4 method for signature 'character'
str2dig(x, split = "", ...)
## S4 method for signature 'list'
str2dig(x, split = "", num.cores = 1L, tasks = 0L, verbose = FALSE, ...)
```

# Arguments

x A character string or a list/ of character strings of numeric/digit symbols.

split The same as in strsplit

... Further parameters for strsplit.

 $\verb"num.cores", tasks"$ 

Parameters for parallel computation using package BiocParallel-package: the number of cores to use, i.e. at most how many child processes will be run simultaneously (see bplapply and the number of tasks per job (only for Linux OC)

OS).

verbose If TRUE, prints the function log to stdout.

# Value

A integer vector or a list of integer vectors.

translation 75

### Author(s)

Robersy Sanchez https://genomaths.com

### **Examples**

```
## A integer vector
str2dig("12231456247")

## A list of integer vectors
str2dig(list(num1 = "12231456247", num2 = "521436897"))
```

translation

Translation of DNA/RNA sequences

# Description

This function extends translate function to include letters that are frequently found in the DNA sequence databases to indicate missing information and are not part of the the DNA/RNA alphabet. Also, it is able to process sequences as just simple 'character' objects.

### Usage

```
translation(x, ...)
## S4 method for signature 'character'
translation(
    X,
    genetic.code = getGeneticCode("1"),
    no.init.codon = FALSE,
    if.fuzzy.codon = "error"
)

## S4 method for signature 'BioString'
translation(
    X,
    genetic.code = getGeneticCode("1"),
    no.init.codon = FALSE,
    if.fuzzy.codon = "error"
)
```

#### **Arguments**

```
x A character string or the same arguments given to function translate.
... Not in use yet.
genetic.code The same as in translate
no.init.codon, if.fuzzy.codon
Used only if 'x' is not a 'character' object. The same as in translate.
```

76 translation

### **Details**

If argument 'x' belong to any of the classes admitted by function translate, then this function is called to make the translation.

### Value

The translated amino acid sequence.

### Author(s)
